Title: Rivers and Stream Investigations
- Wild Trout Population Surveys

Contract Period: July 1, 1997 to June 30, 1998

ABSTRACT

The primary goal of this study was to determine the distribution of bull trout *Salvelinus confluentus*.

During summer 1997, project personnel surveyed 71 sites in 45 drainages to assess fish populations and size structure of salmonid species. We electrofished 42 sites on 26 North Fork Salmon River tributaries and 29 sites on 19 Salmon River tributaries, using multiple-pass removals to derive population estimates. Fish less than 70 mm total length were not included in the population estimates because they had a lower probability of capture by electrofishing.

We captured 915 trout. In order of abundance, they were rainbow trout/steelhead *Oncorhynchus mykiss*, westslope cutthroat trout *O. clarki lewisi*, bull trout, rainbow trout/westslope cutthroat trout hybrids, and brook trout *S. fontinalis*.

In Valley Creek, we removed 16,025 brook trout to reduce brook trout numbers, and transplanted 711 westslope cutthroat trout to reestablish a fishable population of westslope cutthroat trout. The Department also transplanted 215 bull trout into Valley Creek.

Project staff continued rainbow trout spawning ground surveys in the upper Lemhi River to monitor the benefits of Model Watershed sponsored habitat improvement projects and changes in fishing regulations. A substantial increase in redds was noted in 1998 compared to previous years.

OBJECTIVES

1. Determine species composition, relative abundance, and size structure of salmonid populations in selected Salmon River and North Fork Salmon River tributaries, with emphasis on bull trout *Salvelinus confluentus*.
2. Determine the effectiveness of multiple pass electrofishing in reducing brook trout *S. fontinalis* abundance and reestablishing westslope cutthroat trout *Oncorhynchus clarki lewisi* in Valley Creek.
3. Determine baseline production levels of resident rainbow trout *O. mykiss* in the upper Lemhi River and monitor the effects of harvest restrictions and habitat improvement projects.

STUDY AREA AND METHODS

Salmon River Tributaries and North Fork Salmon River Tributaries

We used a Smith-Root SR-15 backpack unit and attempted to catch all sizes of game and non-game fish, setting block nets at either end of each transect unless natural barriers were present (i.e. waterfall, beaver dam or high gradient riffle). Transects ranged from 30-77 meters in length. We made passes going upstream, with each consecutive pass immediately after and with equal effort to the previous pass. Generally made two passes were sufficient, with a third occasionally needed to achieve reduction.

We measured fish to total length, placed them in holding pens, and monitored them for recovery until all passes were completed. Once electrofishing was completed, each fish was returned to the habitat where it was captured. We made no attempt to differentiate between rainbow trout and steelhead trout.

Density estimates were reported as fish sampled per 100m² of transect surface area and were calculated using Microfish population software (Van Deventer and Platts, 1989). Because small fish are not efficiently sampled by electrofishing, we used only fish 70 mm and larger in the population estimates. If the sample size or distribution of fish among passes was insufficient for calculation of estimates using Microfish, we listed the sampled fish as 'observed', and did not include them in population estimate results.

Valley Creek

Valley Creek is small enough to be electrofished by wading. One or two, 2-man teams used a Smith-Root SR-15 backpack electrofishing unit operated at 200-300 V, and 3 amps of pulsed DC current. The project site began 9.6 km above the confluence of Valley Creek and the Salmon River, and continued 11.2 km upstream. The lower 0.8 km of several tributaries

was also included. We removed all brook trout captured.

Upper Lemhi River

In 1994 the Department began informal redd counts on Big Springs Creek, a tributary to the Lemhi River near Leadore. By 1997 we had established three transect areas to monitor long term trends in fish populations: two transects on Big Springs Creek and one on the mainstem Lemhi River. The two sites on Big Springs Creek include those portions of the creek that flow through the Karl Tyler and Darwin Neibaur ranches. The mainstem Lemhi River site includes the Merrill Beyeler Ranch from the upper fence approximately 100 meters upstream of the upper water gap to the lower fenced boundary.

We conduct redd counts annually between April 21 and May 3. Most spawning has ceased by the third week of April, therefore, the counts should represent the total spawning activity for the year.

RESULTS AND DISCUSSION

Salmon River Tributaries and North Fork Salmon River Tributaries

Appendices A, B, C, and D list survey sites, sampling dates, and transect measurements. We did not survey Crone Gulch due to low water. Detailed site measurements of streams are available at the Idaho Department of Fish and Game office in Salmon, Idaho.

We sampled 915 trout: 36% rainbow/steelhead trout, 27% westslope cutthroat trout, 20% bull trout, 14% rainbow trout/westslope cutthroat trout hybrids, and 3% brook trout. Appendices E and F list observed salmonid densities for each site by species and drainage. Combined density estimates within a stream are available at the Idaho Department of Fish and Game office in Salmon, Idaho.

Tables 1, 2, 3, 4 and 5 list population estimates with confidence intervals by species and by survey site. Appendices G, H, I, and J show population estimates with corresponding confidence intervals for all species of trout combined.

The East Fork Spring Creek had the highest estimated densities of rainbow/steelhead trout. The East Fork Pierce Creek and Salzer Creek had the highest estimated densities of westslope cutthroat trout. Carmen Creek had the highest estimated densities of bull trout. Sage and Colson creeks had the highest estimated densities of hybrid rainbow trout/cutthroat trout. We observed brook trout in only three streams (Hull, Dahlenega and Threemile creeks) and in low densities.

Hull Creek, L	6	6	4.0	7.1	0.667
Hull Creek, U	3	3	1.3	3.8	0.800

^a Brook trout were also captured in Dahlongega and Threemile creeks; however, due to small sample sizes, no population estimates could be calculated.

^b L = lower site, M = middle site, U = upper site.

^c Only brook trout > 70 mm were used in estimates.

Tables 6, 7, 8, 9, and 10 summarize total length data for each trout species. The North Fork Salmon River and the East Fork Owl Creek contained larger rainbow trout than other areas sampled. Indian Creek and the North Fork Salmon River contained larger westslope cutthroat trout. Spring Creek and the West Fork of the North Fork Salmon River contained larger bull trout. Indian and Twin creeks contained larger rainbow trout/westslope cutthroat trout hybrids. The largest brook trout (230 mm) was in Hull Creek. Dahlenega Creek also contained large brook trout.

Valley Creek

There were increasing numbers westslope cutthroat trout as we moved upstream into the higher gradient headwaters. Sampling was in late August, September, and October. Removal seemed especially effective in October when pairs of spawning brook trout were taken off their redds and the redds destroyed.

The Idaho Department of Fish and Game transferred 711 westslope cutthroat trout and 215 bull trout from several area tributaries to repopulate Valley Creek with native stocks (Table 11). In 1998 we plan to implant radio transmitters in several stocks of westslope cutthroat trout and monitor their movements in or out of Valley Creek. This will show if one stock is more likely to remain in Valley Creek than the others.

Upper Lemhi River

Table 12 shows redd counts recorded since 1994. In 1998 there was a substantial increase in counts at all sites. These increases probably had several causes: (1) fishing regulations on the Lemhi River changed from no size limit to a 14-in minimum size restriction, (2) we completed several habitat improvement projects, and (3) Lemhi county experienced a reprieve in drought conditions in the late 1980s and early 1990s. Regional personnel will continue to monitor these population trends.

Table 6. Total lengths of rainbow/steelhead trout sampled in North Fork Salmon and Salmon rivers tributaries.

1997 ANNUAL PERFORMANCE REPORT

State of: Idaho

Program: Fishery Management F-71-R-22

Project II: Technical Guidance

Subproject II-H: Salmon Region

Contract Period: July 1, 1997 to June 30, 1998

ABSTRACT

In 1997, we provided technical assistance to all state and federal agencies upon request. Comments were submitted to several agencies and private entities concerning stream alterations, bank stabilization, mining operations and reclamation plans, fish rearing proposals, private ponds, water right applications, grazing allotments, timber sales, highway reconstruction, habitat improvements, bridge construction, and hydropower projects. We conducted on-site inspections of proposed, on-going, and completed projects.

Project staff provided technical assistance at angler informational meetings, gave school presentations, and updated the Salmon Region portion of the 1-800-ASK-FISH program. We also responded in person, by telephone, and by mail to inquiries by the general public about fishing opportunities, techniques, regulations, and area specifics.

Authors

Mark Liter
Regional Fishery Biologist

Mike Larkin
Regional Fishery Manager

OBJECTIVES

1. Assist the Idaho Department of Water Resources, the Idaho Department of Lands, the U.S. Army Corps of Engineers and other state, federal, local, and private entities in evaluating the effects of habitat manipulation on fish and fish habitat.
2. Recommend procedures that minimize adverse effects of stream course alterations on aquatic habitat and fish.
3. Provide information on all aspects of fisheries and aquatic habitat as requested.

METHODS

Project staff responded to all requests for data, expertise, and recommendations from individuals, government agencies, and corporations. We attended meetings, conducted field inspections, and generated appropriate responses.

RESULTS

In 1997, we responded in writing to requests for technical assistance or comments on water and fishery-related matters as follows:

<u>Agency</u>	<u>Number of Requests</u>
Idaho Outfitters and Guides Licensing Board	2
US Forest Service	11
Idaho Department of Water Resources	46
US Department of Transportation	2
Private and Miscellaneous	11
US Army Corps of Engineers	14
Custer/Lemhi County Commissioners	2
Shoshone-Bannock Tribe	1
US Bureau of Reclamation	1

Interagency contacts were mainly by telephone. We usually responded to stream alteration proposals by meeting with the applicant at the site, determining the nature of the situation, and sending written comments to permitting agency. Because the Salmon Region is so remote, project personnel were often the only State agency representatives available to

conduct on-site inspections.

Staff responded to numerous inquiries from the public (by telephone, letter, and in person) about when, where, and how to fish in the Region, ranging from steelhead angling to alpine lake fishing. We reported weekly steelhead fishing results on the local radio station and in area newspapers during the season.

Project biologists spent approximately 25 days helping to develop a memorandum of agreement in Custer County pertaining to river restoration projects. A habitat project on Hannah Slough made it clear that a unified plan for river restoration projects was needed. Custer County residents decided to write a restoration plan for the entire 12-mile section of the Salmon River near Challis, Idaho. To guide this process from a local level, the county formed the Custer County Watershed Group. We helped develop an overview plan and are now in the process of acquiring funding.

We acquired a \$100,000 grant through the Idaho Fish and Wildlife Foundation for stream restoration work on Agency Creek, East Fork Salmon River and Hannah Slough. Work on Agency Creek and the East Fork Salmon River is in progress.

Fisheries personnel spent 40 days working on cooperative river restoration projects with the Lemhi Model Watershed Project. Most of the projects were on the East Fork Salmon River, with a few projects on the Lemhi and Pahsimeroi rivers.

The Salmon Region has no Information and Education or Regional Conservation Education personnel. During 1997 Salmon Region fisheries personnel conducted 33 presentations to approximately 375 students in four different schools.

RECOMMENDATIONS

1. Continue to provide technical guidance on issues involving fishery resources in the Salmon Region.
2. Hire additional personnel to administer habitat issues and to meet information and education needs.

1997 ANNUAL PERFORMANCE REPORT

State of: Idaho

Program: Fishery Management F-71-R-22

Project III: Habitat Management

Subproject III-H: Salmon Region

Contract Period: July 1, 1997 to June 30, 1998

ABSTRACT

We initiated habitat projects on several rivers and streams in the Salmon Region. Project funding came from several sources (Blackbird Mine mitigation, National Fish and Wildlife Foundation, and Natural Resource Conservation Service). Fencing projects on the Lemhi, Pahsimeroi, and East Fork Salmon rivers will provide riparian protection for approximately 12 river miles. Stream bank restoration work on Agency Creek, a Lemhi River tributary, involved back-sloping vertical eroding banks and reseeding with grasses and willows. Modified irrigation diversions on Agency Creek and the Pahsimeroi River now allow fish passage.

Fishery biologists helped develop a restoration plan for 12 miles of the Salmon River near Challis, Idaho. The Department will use this overview plan to educate landowners and community leaders on how on to restore a healthy river corridor. It will form the basis for developing site-specific restoration plans. We are requesting funds from the Bonneville Power Administration and U.S. Corps of Engineers for fencing, dike renovation or removal, and bank stabilization work.

1997 ANNUAL PERFORMANCE REPORT

State Of: Idaho

Program: Fisheries Management F-71-R-22

Project IV: Population Management

Subproject IV-H: Salmon Region

Contract Period: July 1, 1997 to June 30, 1998

ABSTRACT

In summer of 1997, the Salmon Region stocked 80,400 fry in 129 mountain lakes in the Sawtooth National Recreation Area and Challis National Forest. Species stocked included 6,150 arctic grayling *Thymallus arcticus*, 7,750 rainbow trout *Oncorhynchus mykiss*, and 67,500 westslope cutthroat trout *O. clarki lewisi*. We used a Cessna-185 fixed-wing aircraft to stock 97 of the 129 Salmon Region lakes at a cost of \$18.97 per lake.

Project personnel removed brook trout *Salvelinus fontinalis* from Carlson Lake during May 1997 to reduce the number of brook trout in the lake and increase growth in remaining fish. Gill netting removed 999 brook trout in 466.4 diel net hours (2.14 fish/hr). The estimated number of brook trout in Carlson Lake was 3,599 fish.

OBJECTIVE

Maintain a viable high mountain lake fishery in the Salmon Region.

METHODS

The Department contracted with McCall Air Taxi from McCall, Idaho to stock Salmon Region high mountain lakes with a Cessna-185 fixed-wing aircraft. The cost of stocking was \$18.97 per lake.

RESULTS

In summer of 1997, the Salmon Region stocked 80,400 fry in 129 mountain lakes in Sawtooth National Recreation Area and Challis National Forest. Species stocked included 6,150 arctic grayling *Thymallus arcticus*, 7,750 rainbow trout *Oncorhynchus mykiss*, and 67,500 westslope cutthroat trout *O. clarki lewisi*. We stocked 97 of the 129 Salmon Region lakes by air. McCall Hatchery stocked 11 Salmon Region lakes. Volunteers stocked 21 lakes, donating an estimated 125 hours. Tables 1 and 2 summarize stocking records for each lake.

DISCUSSION

The Department has purchased Washoe Park, Montana westslope cutthroat trout for stocking in Idaho lakes. This stock performed very poorly this year. Of the 207,500 eyed eggs received, 151,400 (73%) hatched. Many of these fry failed to go on feed and died, leaving 67,500 survivors to be planted. Considering their poor performance at Sawtooth Hatchery, we assumed that most, if not all, Montana westslope cutthroat trout fry died after stocking. We are seeking an alternate westslope cutthroat source.

CARLSON LAKE

INTRODUCTION

Carlson Lake is a popular fishing lake accessible by an unmaintained road located in T11N, R23E, S17 at approximately 8,000 ft elevation. It drains into Double Spring Creek, a tributary of the Pahsimeroi River. The lake has one inlet and outlet that are active during high water years (Liter and Lukens 1994). Brook trout *Salvelinus fontinalis* is the only game species present in the lake.

* C2 = westslope cutthroat trout; GR = grayling; K1 = rainbow trout, domestic Kamloops strain.

Historically, Carlson Lake produced 0.9 to 1.4 kg brook trout, but by 1975 anglers were concerned about the decline in numbers of these large fish (Kent Ball, intradepartmental memos 1975). Gill netting surveys show the average size of brook trout in Carlson Lake has declined from 224 mm in 1981 to 192 mm in 1997 (Figures 1-5).

OBJECTIVES

1. Reduce the number of brook trout to allow remaining fish to grow larger, enhancing angler interest in the fishery.
2. Obtain information on the current size and age structure of brook trout in Carlson Lake and document changes in size structure over time.

METHODS

During May 1997 project personnel used eleven 1.8 m X 38.1 m variable mesh gill nets to catch and remove brook trout from Carlson Lake. We set the nets with a rubber raft, spacing them evenly around the lake, perpendicular to the shore with the smallest mesh size towards shore. The first set was approximately 4.5 hours, while the remaining three were approximately 12 hours long. The first and third sets were daylight samples, the second and fourth sets were night samples.

We measured total lengths and collected otoliths from 33 brook trout and stored the otoliths in glycerin until processing them. At that time otoliths were heated, cracked and examined under a dissecting scope.

Microfish 3.0 software (Van Deventer and Platts 1989) calculated a population estimate. An ANOVA tested for differences in catch rates between all sets, and pair-wise comparisons tested for differences between the catch rate of two sets. A t-test determined if differences in catch rate existed between night and daytime sets. Statistica 5.0 software (Stat Soft, Inc. 1984) calculated all statistics.

RESULTS

We removed 999 brook trout from Carlson Lake during 466.4 net hours. Carlson Lake contained an estimated 3,599 brook trout (95% confidence intervals 1496 to 5701). Total lengths ranged from 118 to 240 mm with an average size of 192 mm (Figure 5).

Catch rates per set ranged from 0.81 to 3.2 fish/h. Catch rates varied significantly between sets ($p = 0.0083$) and between night and day sets (mean day = 1.5 fish/h, mean night = 2.5 fish/h ($p = 0.0217$)). The catch rates of sets 1 and 2 differed significantly from

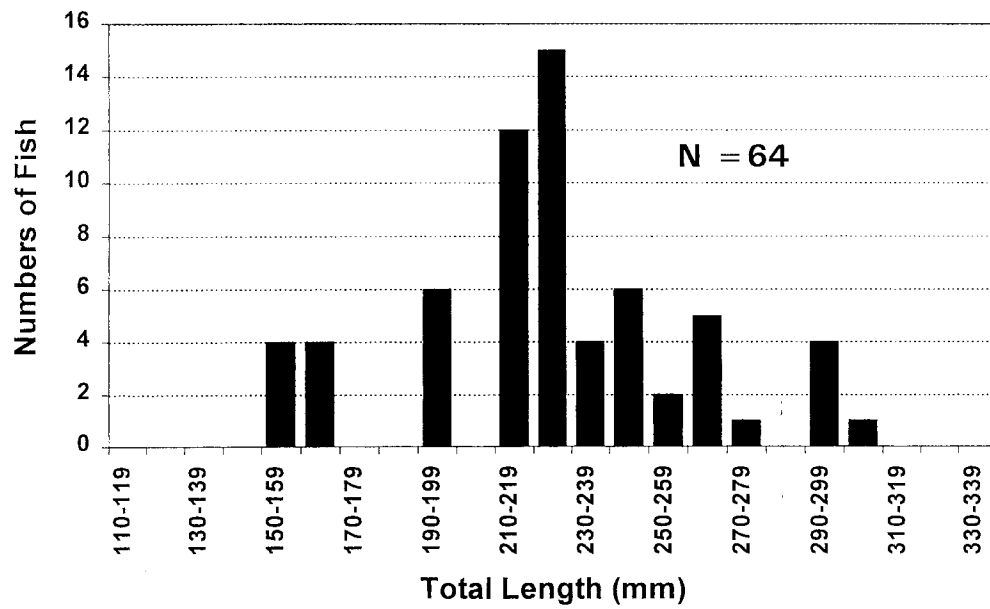

Figure 1. Length frequency of brook trout in Carlson Lake, 1981.

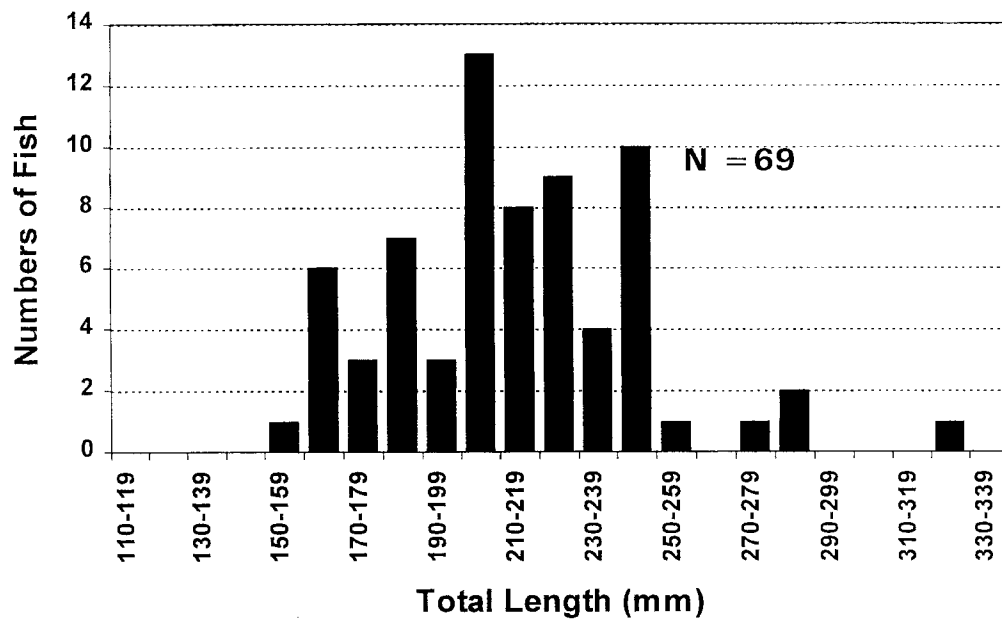

Figure 2. Length frequency of brook trout in Carlson Lake, 1992.

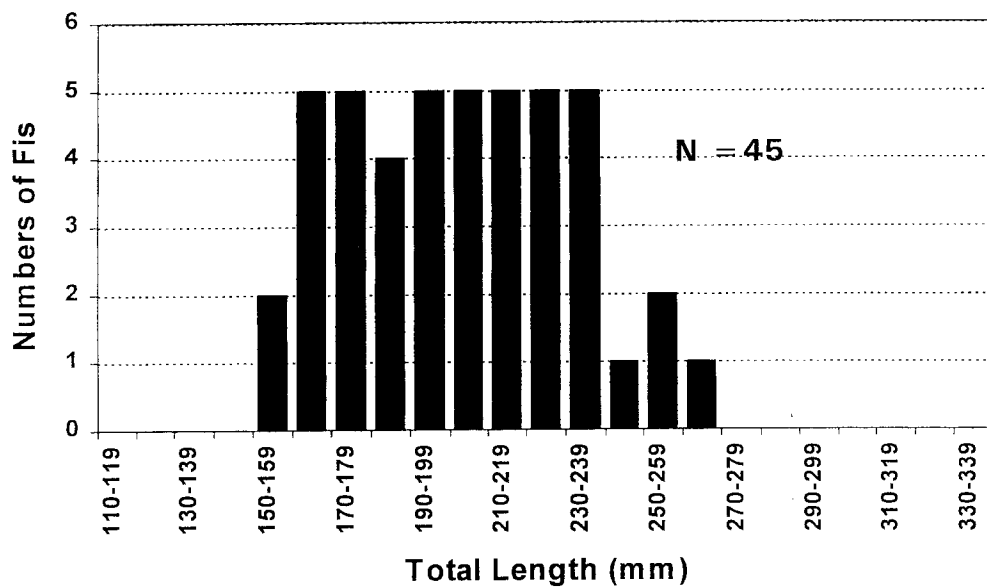

Figure 3. Length frequency of brook trout in Carlson Lake, 1993.

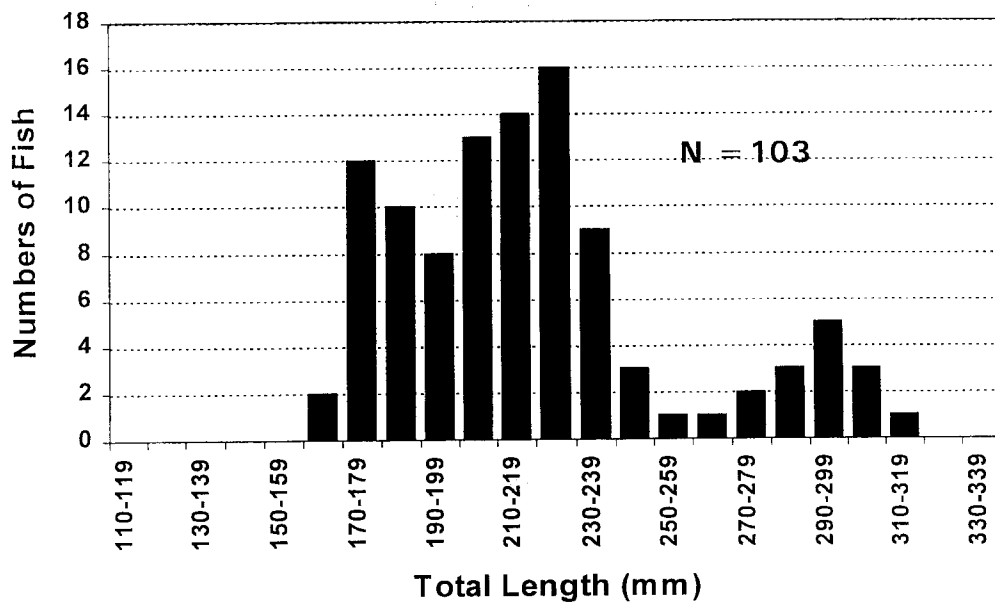

Figure 4. Length frequency of brook trout in Carlson Lake, 1996.

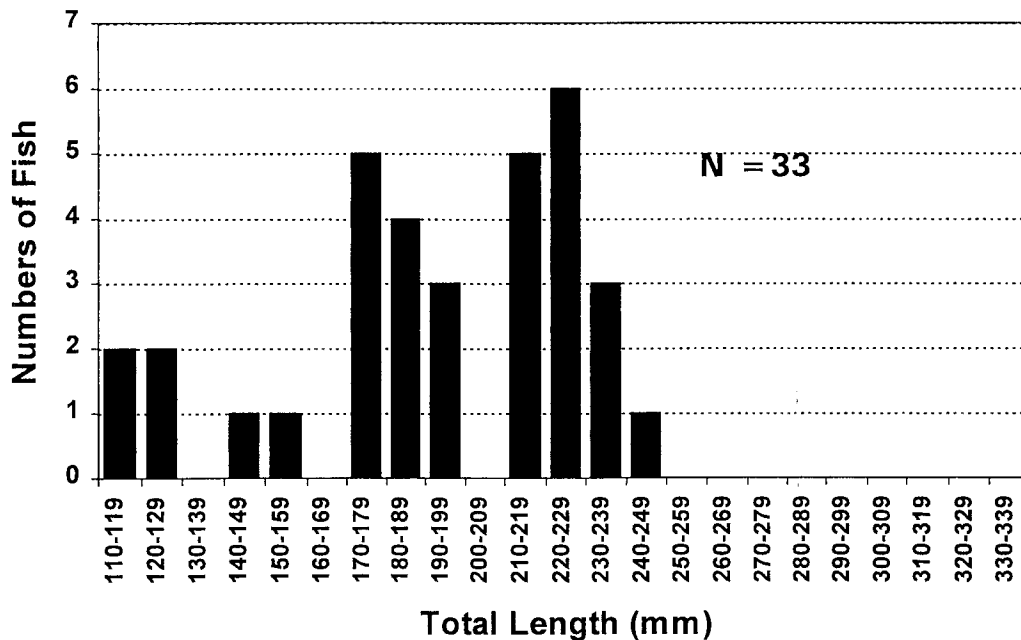

Figure 5. Length frequency of brook trout in Carlson Lake, 1997.

that of set 3 ($p = 0.005$) and ($p = 0.003$) respectively. Length frequency histograms had relatively similar length frequency distributions in most sample years (Figures 1-5). Otoliths could not be read with any confidence due to uneven breakage, and extremely tight banding of the annuli.

DISCUSSION

Catch rates between sets were highly variable (range 0.8 to 3.1 fish/h) (Figure 6). The population estimate for this lake is probably low due to the high variability in catch rates between gill net sets and inability of the technique to sample small fish. Statistical differences between day and night sets suggest that brook trout were more active at night in areas sampled by gill nets or they avoided gill nets during the day. We might obtain more precise population estimates by sampling only during dark hours and ensuring that all set periods are equally long.

The mean length of brook trout has decreased by 32 mm since 1981, presumably due to overpopulation and increased competition for food. Frequency of larger brook trout varies in sample years from 1981 to 1997, but no sample fish exceeded 329 mm (Figures 1-5). We have had mixed success with introducing predators into high mountain lakes to change the size structure of brook trout populations. In lakes where brown trout *Salmo trutta* were introduced, size structure did not improve, but the relative weight index and k factor both improved significantly (Janssen and Patterson 1993). In 1993, the Department stocked 702

Gerrard strain rainbow trout *Oncorhynchus mykiss* (average total length 254 mm) in Carlson Lake (Liter and Lukens 1996). This introduction apparently failed, as rainbow trout are no longer present in the lake and the brook trout population is still stunted.

The Idaho Fish and Game Commission recently increased the brook trout bag limit to 16 fish. This may help increase the average size fish. With the apparent failure of predator introductions to counteract stunting, the best approach may be to continue gillnetting efforts, employ an ichthyocide (piscicide), maintain a high bag limit, and improve access for anglers. It will be some time before management strategies show results.

RECOMMENDATIONS

1. Continue intensive gillnetting efforts to increase average size.
2. Increase angler pressure by advertising the fishery and improving road access.
3. Continue the increased bag limit (16) on brook trout in Carlson Lake.
4. Investigate the feasibility of chemical treatment on at least the littoral areas of Carlson Lake to concentrate on young of year fish as these are not vulnerable to gill nets.
